Approximation Algorithms

Lecture 5:

LP-based Approximation Algorithms for SetCover

Part I:

SETCOVER as an ILP

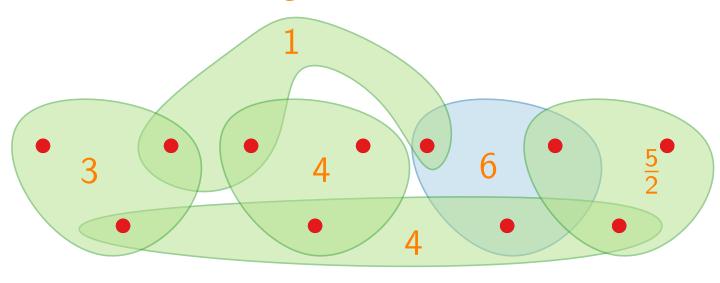

SetCover as an ILP

$$\begin{array}{ll} \textbf{minimize} & \displaystyle\sum_{S \in \mathcal{S}} c_S x_S \\ \textbf{subject to} & \displaystyle\sum_{S \ni u} x_S \geq 1 \quad u \in \mathcal{U} \\ x_S \in \{0,1\} \quad S \in \mathcal{S} \end{array}$$

Ground set *U*

Family $S \subseteq 2^{U}$ with $\bigcup S = U$

Costs $c: S \to \mathbb{Q}^+$

Find cover $S' \subseteq S$ of U with minimum cost.

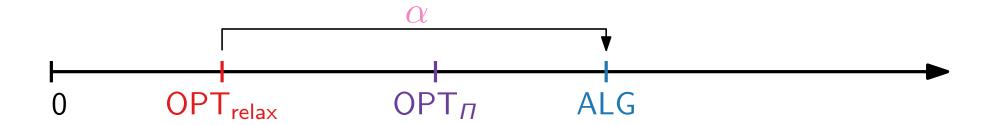

Approximation Algorithms

Lecture 5:

LP-based Approximation Algorithms for SetCover

Part II: LP-Rounding

Technique I) LP-Rounding

Consider a minimization problem Π in ILP form.

Compute a solution for the LP-relaxation.

Round to obtain an integer solution for Π .

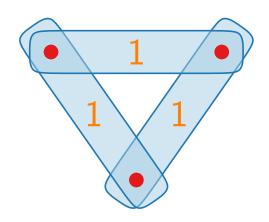

Difficulty: Ensure the **feasiblity** of the solution.

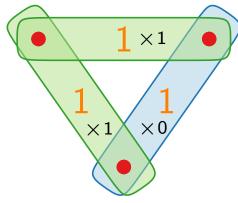

Approximation factor: $ALG/OPT_{\Pi} \leq ALG/OPT_{relax}$.

SetCover - LP-Relaxation

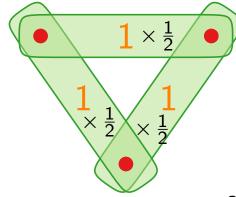

minimize
$$\sum_{S \in \mathcal{S}} c_S x_S$$
subject to
$$\sum_{S \ni u} x_S \ge 1 \quad u \in U$$
$$x_S \ge 0 \qquad S \in \mathcal{S}$$

Optimal?

integer: 2

fractional: $\frac{3}{2}$

LP-Rounding: Approach I

minimize
$$\sum_{S \in \mathcal{S}} c_S x_S$$
 subject to
$$\sum_{S \ni u} x_S \ge 1 \quad u \in U$$

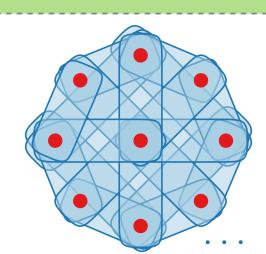

$$x_S \ge 0 \qquad S \in \mathcal{S}$$

LP-Rounding-One(U, S, c)

Compute optimal solution x for LP-relaxation. Round each x_s with $x_s > 0$ to 1.

- Generates a valid solution.
- Scaling factor arbitrarily large.

Use frequency f

LP-Rounding: Approach II

minimize
$$\sum_{S \in \mathcal{S}} c_S x_S$$
 subject to
$$\sum_{S \ni u} x_S \ge 1 \quad u \in U$$

$$x_S \ge 0 \qquad S \in \mathcal{S}$$

LP-Rounding-Two(U, S, c)

Compute optimal solution x for LP-relaxation. Round each x_s with $x_s \ge 1/f$ to 1; remaining to 0.

Let *f* be the frequency of (i.e., the number of sets containing) the most frequent element.

Theorem. LP-Rounding-Two is a factor-*f* approximation algorithm for SetCover.

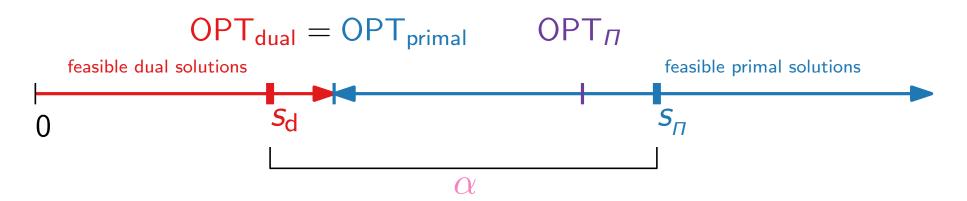

Approximation Algorithms

Lecture 5:

LP-based Approximation Algorithms for SetCover

Part III:
The Primal-Dual Schema

Technique II) Primal-Dual Approach

Consider a minimization problem Π in ILP form.

- Start with (trivial) feasible dual solution and infeasible primal solution (e.g., all variables = 0).
- Compute dual solution s_d and integral primal solution s_n for Π iteratively: Increase s_d according to CS and make s_n "more feasible".

Approximation factor $\leq obj(s_n)/obj(s_d)$

Advantage: Don't need LP-"machinery"; possibly faster, more flexible.

SetCover - Dual LP

minimize
$$\sum_{S \in \mathcal{S}} c_S x_S$$

subject to
$$\sum_{S \ni u} x_S \ge 1 \qquad u \in U$$

$$x_S \ge 0 \qquad S \in \mathcal{S}$$

maximize
$$\sum_{u \in U} y_u$$
 subject to
$$\sum_{u \in S} y_u \le c_S \quad S \in S$$

$$y_u \ge 0 \qquad u \in U$$

Complementary Slackness

minimize
$$c^{\mathsf{T}} x$$

subject to $Ax \geq b$
 $x \geq 0$

maximize
$$b^{\mathsf{T}} y$$

subject to $A^{\mathsf{T}} y \leq c$
 $y \geq 0$

Theorem. Let $x = (x_1, ..., x_n)$ and $y = (y_1, ..., y_m)$ be valid solutions for the primal and dual program (resp.). Then x and y are optimal if and only if the following conditions are met:

Primal CS:

For each
$$j=1,\ldots,n$$
: $x_j=0$ or $\sum_{i=1}^m a_{ij}y_i=c_j$

Dual CS:

For each
$$i=1,\ldots,m$$
: $y_i=0$ or $\sum_{j=1}^n a_{ij}x_j=b_i$

Relaxing Complementary Slackness

minimize
$$c^{\mathsf{T}} x$$

subject to $Ax \geq b$
 $x \geq 0$

$$\begin{array}{ll} \textbf{maximize} & b^{\mathsf{T}} y \\ \textbf{subject to} & A^{\mathsf{T}} y & \leq c \\ & y & \geq 0 \end{array}$$

Primal CS: Relaxed Primal CS

For each
$$j=1,\ldots,n$$
: $x_j=0$ or $\sum_{i=1}^m a_{ij}y_i=c_j$ $c_j/\alpha \leq \sum_{i=1}^m a_{ij}y_i \leq c_j$

Dual CS: Relaxed Dual CS

For each
$$i=1,\ldots,m$$
: $y_i=0$ or $\sum_{j=1}^n a_{ij}x_j=b_i$ $b_i \leq \sum_{j=1}^n a_{ij}x_j \leq \beta \cdot b_i$

$$\Leftrightarrow \sum_{j=1}^{n} c_{j} x_{j} = \sum_{i=1}^{m} b_{i} y_{i} \quad \Rightarrow \sum_{j=1}^{n} c_{j} x_{j} \leq \alpha \beta \sum_{i=1}^{m} b_{i} y_{i} \leq \alpha \beta \cdot \mathsf{OPT}_{\mathsf{LP}}$$

Primal-Dual Schema

Start with a feasible dual and infeasible primal solution (often trivial).

"Improve" the feasibility of the primal solution...

...and simultaneously the objective value of the dual solution.

Do so until the relaxed CS conditions are met.

Maintain that the primal solution is integer-valued.

The feasibility of the primal solution and the relaxed CS conditions provide an approximation ratio.

Relaxed CS for SetCover.

minimize
$$\sum_{S \in \mathcal{S}} c_S x_S$$

subject tomaximize
$$\sum_{u \in \mathcal{U}} y_u$$

subject tosubject to
$$\sum_{u \in \mathcal{S}} y_u \le c_S$$
$$x_S \ge 0$$
$$S \in \mathcal{S}$$

maximize
$$\sum_{u \in U} y_u$$

subject to
$$\sum_{u \in S} y_u \le c_S \quad S \in S$$

$$y_u \ge 0 \qquad u \in U$$

(Unrelaxed) primal CS:
$$x_S \neq 0 \Rightarrow \sum_{u \in S} y_u = c_S$$

only chooses critical sets

trivial for binary *x* ◀------**Relaxed dual CS:** $y_u \neq 0 \Rightarrow 1 \leq \sum x_s \leq f \cdot 1$

Primal-Dual Schema for SetCover

PrimalDualSetCover(*U*, *S*, *c*)

$$x \leftarrow 0, y \leftarrow 0$$

repeat

Select an uncovered element u.

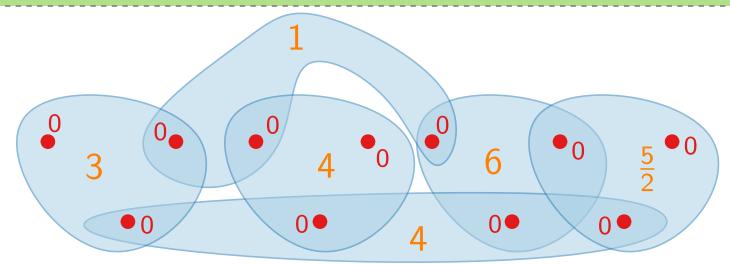

Increase y_u until a set S is critical $(\sum_{u' \in S} y_{u'} = c_S)$.

Select all critical sets and update x.

Mark all elements in these sets as covered.

until all elements are covered.

return x

Primal-Dual Schema for SetCover

PrimalDualSetCover(*U*, *S*, *c*)

$$x \leftarrow 0, y \leftarrow 0$$

repeat

Select an uncovered element u.

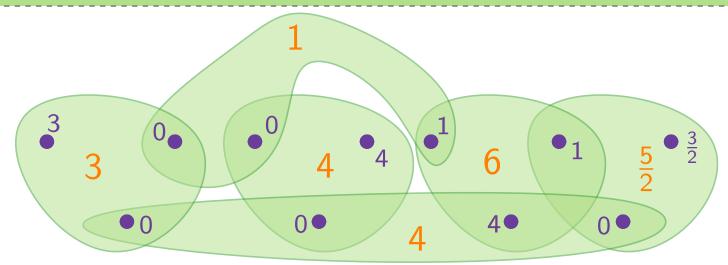

Increase y_u until a set S is critical $(\sum_{u' \in S} y_{u'} = c_S)$.

Select all critical sets and update x.

Mark all elements in these sets as covered.

until all elements are covered.

return x

Primal-Dual Schema for SetCover

PrimalDualSetCover(*U*, *S*, *c*)

$$x \leftarrow 0, y \leftarrow 0$$

repeat

Select an uncovered element u.

Increase y_u until a set S is critical $(\sum_{u' \in S} y_{u'} = c_S)$.

Select all critical sets and update x.

Mark all elements in these sets as covered.

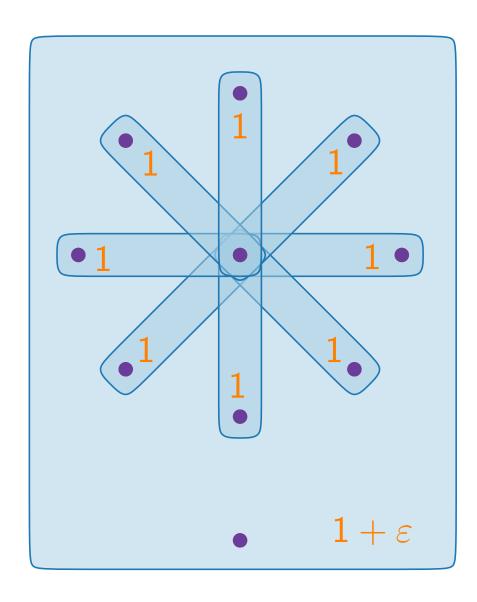

until all elements are covered.

return x

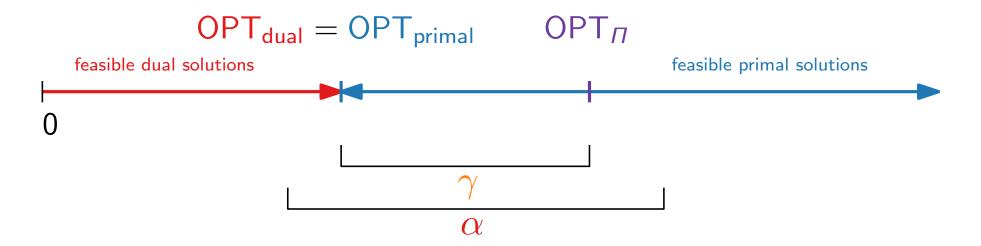

1

Theorem. PrimalDualSetCover is a factor-f approximation algorithm for SetCover. This bound is tight.

Tight Example

Integrality Gap

Consider a minimization problem Π in ILP form.

Dual methods (without outside help) are limited by the integrality gap of the LP-relaxation

$$\alpha \ge \gamma = \sup_{I} \frac{\mathsf{OPT}_{\Pi}(I)}{\mathsf{OPT}_{\mathsf{primal}}(I)}$$

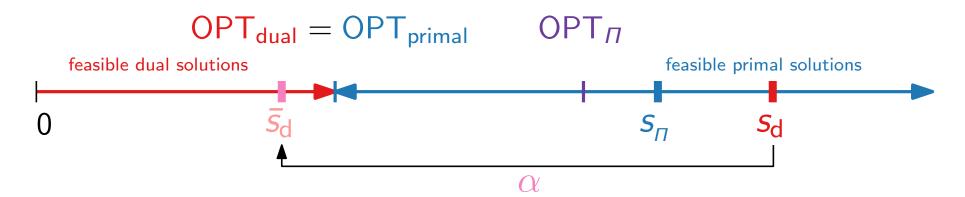

Approximation Algorithms

Lecture 5:

LP-based Approximation Algorithms for SetCover

Part IV: Dual Fitting

Technique III) Dual Fitting

Consider a minimization problem Π in ILP form.

Combinatorial algorithm (e.g., greedy) computes feasible primal solution s_{Π} and infeasible dual solution s_{d} that completely "pays" for s_{Π} , i.e., $obj(s_{\Pi}) \leq obj(s_{d})$.

Scale the dual variables \rightsquigarrow feasible dual solution \overline{s}_d .

$$\Rightarrow \operatorname{obj}(s_{\Pi})/\alpha \leq \operatorname{obj}(s_{d})/\alpha = \operatorname{obj}(\bar{s}_{d}) \leq \operatorname{OPT}_{\operatorname{dual}} \leq \operatorname{OPT}_{\Pi}$$

 \Rightarrow Scaling factor α is approximation factor :-)

Dual Fitting for SetCover

Combinatorial (greedy) algorithm (see Lecture #2):

```
GreedySetCover(U, S, c)
    C \leftarrow \emptyset
   \mathcal{S}' \leftarrow \emptyset
   while C \neq U do
           S \leftarrow \text{Set from } S \text{ that minimizes } \frac{c(S)}{|S \setminus C|}
          foreach u \in S \setminus C do
          \mathsf{price}(u) \leftarrow \tfrac{c(S)}{|S \setminus C|}
        C \leftarrow C \cup S<br/>S' \leftarrow S' \cup \{S\}
   return S'
                                                                          // Cover of U
```

Reminder: $\sum_{u \in U} \operatorname{price}(u)$ completely pays for S'.

New: LP-based Analysis

Observation. For each $u \in U$, price(u) is a dual variable But this dual solution is in general not feasible.

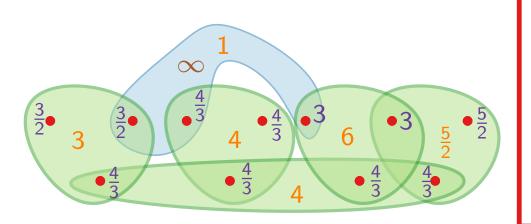

Homework exercise: Construct instance where some ${\it S}$ are "overpacked" by factor $\approx H_{|{\it S}|}$.

Dual-fitting trick:

Scale dual variables such that no set is overpacked.

Take $\bar{y}_u = \text{price}(u) / \mathcal{H}_k$. $(k = \text{cardinality of largest set in } \mathcal{S}.)$

The greedy algorithm uses *these* dual variables as lower bound for OPT.

Proof. To prove: No set is overpacked by \overline{y} .

Let $S \in S$ and $\ell = |S| \le k$.

Let u_1, \ldots, u_ℓ be the elements of S — in the order in which they are covered by greedy.

Consider the iteration in which u_i is covered.

Before that, $\geq \ell - i + 1$ elem. of S are uncovered.

So price
$$(u_i) \leq c(S)/(\ell - i + 1)$$
. $= \mathcal{H}_{\ell} \leq \mathcal{H}_{k}$
 $\Rightarrow \bar{y}_{u_i} \leq \frac{c(S)}{\mathcal{H}_{k}} \cdot \frac{1}{\ell - i + 1} \Rightarrow \sum_{i=1}^{\ell} \bar{y}_{u_i} \leq \frac{c(S)}{\mathcal{H}_{k}} \cdot \left(\frac{1}{\ell} + \dots + \frac{1}{1}\right)$

Lemma.

The vector $\bar{y} = (\bar{y}_u)_{u \in U}$ is a feasible solution for the dual LP.

Result for Dual Fitting

Theorem. GreedySetCover is a factor- \mathcal{H}_k approximation algorithm for SetCover, where $k = \max_{S \in \mathcal{S}} |S|$.

Proof.
$$ALG = c(S') \leq \sum_{u \in U} \operatorname{price}(u) = \mathcal{H}_k \cdot \sum_{u \in U} \overline{y}_u \leq$$

$$\leq \mathcal{H}_k \cdot \operatorname{OPT}_{\operatorname{relax}}$$

$$\leq \mathcal{H}_k \cdot \operatorname{OPT} \quad \Box$$

Strengthened bound with respect to $OPT_{relax} \leq OPT$.

Dual solution allows a per-instance estimation $c(\mathcal{S}')/\mathsf{OPT}_{\mathsf{relax}}$ of the quality of the greedy solution

... which may be stronger than the worst-case bound \mathcal{H}_k .
